

# CLASS FIELD THEORY

COURSE: RENÉ SCHOOF AND PETER STEVENHAGEN  
NOTES: ROSS PATERSON

DISCLAIMER. These notes were taken live during lectures. In particular, any mistakes are the fault of the transcriber and not of the lecturer.

## LECTURE 1 (STEVENHAGEN)

Recall the Fermat equation

$$x^n + y^n = z^n / \mathbb{Z}.$$

Note, an observation due to the likes of Kummer, that if we allow ourselves complex numbers then we can factorise

$$y^m = \prod_{i=1}^m (Z - \zeta_m^i X),$$

where  $\zeta_m = e^{2\pi i/m}$ . Kummer discovered that in fact we don't need to look at all of the complex numbers, but in fact we should look at 'number rings'  $\mathbb{Z}[\zeta_m]$ .

**Algebraic Number Theory.** Algebraic number theory is essentially doing arithmetic like we do for  $\mathbb{Z}$ , but now for number rings. These number rings live in number fields, much like  $\mathbb{Z}$  lives in  $\mathbb{Q}$ , and in fact we end up with a diagram

$$\begin{array}{c} K = \mathbb{Q}(\alpha) \supset \mathcal{O}_K \supseteq \mathbb{Z}[\alpha] \\ \uparrow n \\ \mathbb{Q} \supset \mathbb{Z} \end{array}$$

where  $f = f_{\mathbb{Q}}^{\alpha} \in \mathbb{Z}[X]$  is the minimal polynomial of  $\alpha$ . Some remarks.

- We would like to find  $\mathcal{O}_K$ , the ring of integers, which is free of rank  $n/\mathbb{Z}$ .
- $\mathcal{O}_K$  has unique prime factorisation.
- We have the class group  $\text{Cl}_K = I_K/P_K$ , where  $I_K$  is the group of fractional ideals in  $\mathcal{O}_K$  and  $P_K$  is the group of principal fractional ideals, and this is a finite abelian group.
- We have embeddings

$$\begin{array}{ccc} K & \xrightarrow{\text{complex}} & \mathbb{C} \\ & \searrow \text{real} & \uparrow \\ & & \mathbb{R}, \end{array}$$

say we have  $r$  real embeddings and  $2s$  complex ones (this is always even since for every complex embedding there is the complex conjugate embedding). Then  $r + 2s + n$ .

- $\mathcal{O}_K^{\times} = \mu_K \times \mathbb{Z}^{r+s-1}$ , where  $\mu_K$  is the finite group of roots of unity in  $K$ .

- The discriminant of the minimal polynomial of  $\alpha$ ,  $\Delta(f)$ , is related to the discriminant of the number field,  $\Delta_K$ , by

$$\Delta(f) = [\mathcal{O}_K : \mathbb{Z}[\alpha]]^2 \Delta_K.$$

- There is the Minkowski bound, which tells us that every class in  $\text{Cl}_K$  contains an integral ideal of norm at most the ‘Minkowski constant’  $M_K$ , which is some explicit multiple of  $\sqrt{\Delta_K}$ . More precisely

$$M_K = \left(\frac{4}{\pi}\right)^s \left(\frac{n!}{n^n}\right)^2 \sqrt{\Delta_K}$$

**Cyclotomic Rings.** Ok so let us return to our example of cyclotomic rings. Let  $K_m = \mathbb{Q}(\zeta_m)$ , then the ring of integers is easy:

$$\mathcal{O}_K = \mathbb{Z}[\zeta_m].$$

There is already a natural action of  $R_m = (\mathbb{Z}/m\mathbb{Z})^\times$  on this ring and field. For  $a \in (\mathbb{Z}/m\mathbb{Z})^\times$  we have the map  $\varphi_a : \zeta_m \mapsto \zeta_m^a$ . Thus  $\mathcal{O}_K$  is a  $\mathbb{Z}[R_m]$ -module.

**Splitting of Primes.** Recall we had the diagram

$$\begin{array}{c} K = \mathbb{Q}(\alpha) \supset \mathbb{Z}[\alpha] \\ \uparrow n \\ \mathbb{Q} \supset \mathbb{Z} \end{array}$$

We want to know what ‘lies above a prime  $p \in \mathbb{Z}$ ’, i.e. we want the factorisation

$$p\mathcal{O}_K = \prod_{i=1}^t \mathfrak{p}_i^{e_i}.$$

For  $p \nmid [\mathcal{O}_K : \mathbb{Z}[\alpha]]$ , we can take  $\bar{f} = f \pmod{p}$  and look at its factorisation

$$\bar{f} = \prod_{i=1}^t \bar{g}_i^{e_i} \in \mathbb{F}_p[X],$$

and this gives the correct  $e_i$  and moreover if we choose lifts of the  $\bar{g}_i$  to  $\mathbb{Z}[X]$  then  $\mathfrak{p}_i = \langle p, g_i(\alpha) \rangle$ .

Moreover, for Galois extensions,  $G = \text{Gal}(K/\mathbb{Q})$  acts transitively on  $\{\mathfrak{p} : \mathfrak{p} \mid p\}$ , and  $[K : \mathbb{Q}] = e \cdot f \cdot g$ , where for  $p$  a prime of  $\mathbb{Z}$ :

- $e$  is the ramification index of one (all) of the primes  $\mathfrak{p}$  above  $p$ ;
- $f$  is the residue field degree, i.e. the degree of the extension  $\mathcal{O}_K/\mathfrak{p} =: k_{\mathfrak{p}} \supseteq \mathbb{F}_p$ ;
- $g = \#\{\mathfrak{p} : \mathfrak{p} \mid p\}$ .

For  $\mathfrak{p} \in \{\mathfrak{p} : \mathfrak{p} \mid p\}$ , one takes the stabiliser  $G_{\mathfrak{p}} = \text{stab}_{\mathfrak{p}} \subseteq G$  and calls this the decomposition group. If the extension is unramified (i.e.  $e = 1$ ) then this group is isomorphic via reduction to  $\text{Gal}(k_{\mathfrak{p}}/\mathbb{F}_p) = \langle \text{Frob}_p \rangle$ , where  $\text{Frob}_p$  is the Frobenius map  $x \mapsto x^p$ .

**Example 1.** For cyclotomic fields  $G_{\mathfrak{p}} = \langle p \pmod{m} \rangle$ , and so  $\mathbb{F}_p(\zeta_m)/\mathbb{F}_p$  has degree equal to the order of  $p \in (\mathbb{Z}/m\mathbb{Z})^\times$

**Example 2** (Cyclotomic fields with  $m = 20$ ). Compute for yourselves the following diagrams of subfields.

Note that the associated lattice of subgroups is

**Example 3** (Cyclotomic Fields). We have a correspondence

$$\begin{aligned} (\mathbb{Z}/m\mathbb{Z})^\times &\leftrightarrow \text{Gal}(K_m/\mathbb{Q}) \\ p &\leftrightarrow \text{Frob}_p. \end{aligned}$$

This is actually an example of a more general mapping known as the Artin symbol. Dirichlet proved that there is equidistribution here. That is, for every  $a \in \mathbb{Z}/m\mathbb{Z}^\times$  the set of primes  $p$  such that  $p \equiv a \pmod{m}$  has density  $1/\varphi(m)$ . This is also an example of a more general phenomenon.

**Theorem 4** (Dirichlet(1840's)–Frobenius–Chebotarev(1924)). *Let  $L/K$  be a finite Galois extension of number fields,  $G = \text{Gal}(L/K)$ ,  $C \subseteq G$  be a conjugacy class. Then*

$$\{\mathfrak{p} \text{ of } K : \text{Frob}_{\mathfrak{p}} \in C\}$$

*has density (in an appropriate sense) equal to  $\frac{\#C}{\#G}$ .*

This is a key result which is extremely important, and has many corollaries which are actually more classical, at least than Chebotarev.

**Corollary 5.** *Let  $L/K$  be a finite Galois extension of number fields, then*

$$\{\mathfrak{p} : \mathfrak{p} \text{ splits completely in } L/K\}$$

*has density  $\frac{1}{[L:K]}$ .*

**Corollary 6.** *If all  $p \equiv 1 \pmod{m}$  split in  $L/\mathbb{Q}$  then  $L \subseteq \mathbb{Q}(\zeta_m)$ .*

**Theorem 7** (Kronecker–Weber(middle of the 1800’s)–Hilbert). *Every finite abelian extension of  $\mathbb{Q}$  is cyclotomic. That is, it is contained in a cyclotomic field  $\mathbb{Q}(\zeta_m)$ .*

*key step of proof.* If  $\mathbb{Q} \subseteq L$  is totally unramified (i.e. unramified everywhere) then  $\mathbb{Q} = L$ . Moreover we have a map

$$\mathbb{Z}/m\mathbb{Z}^\times \rightarrow \text{Gal}(L/\mathbb{Q})$$

Given by

$$p \bmod m \mapsto \text{Frob}_p.$$

□

### Main Theorem of Class Field Theory.

**Theorem 8** (CFT). *Let  $K$  be a number field, and  $L/K$  be an abelian extension. Then  $L$  is a class field, i.e. it is contained in a ray class field modulo some modulus  $\mathfrak{m}$ , denoted  $H_{\mathfrak{m}}$ .*

Of course there are plenty of words here that need to be defined and understood, but the point is as follows: There is a ‘ray class group modulo  $\mathfrak{m}$ ’  $\text{Cl}_{\mathfrak{m}}$  generated by some set of primes  $\mathfrak{p} \nmid \mathfrak{m}$  and such that

$$\begin{aligned} \text{Cl}_{\mathfrak{m}} &\rightarrow \text{Gal}(L/K) \\ [\mathfrak{p}] &\mapsto \text{Frob}_{\mathfrak{p}}. \end{aligned}$$

By the end of this week you should hopefully see this as no more complicated than  $\mathbb{Z}/m\mathbb{Z}^\times$ ! Let us see the definition.

**Definition 9.** A modulus of a number field  $K$  is a formal pair  $\mathfrak{m} = \mathfrak{m}_0 \mathfrak{m}_\infty$  where  $\mathfrak{m}_0 \subseteq \mathcal{O}_K$  is a nonzero ideal and  $\mathfrak{m}_\infty$  is a collection of real embeddings of  $K$ . We define the associated ray class group as follows.

$$\text{Cl}_{\mathfrak{m}} = I(\mathfrak{m})/R_{\mathfrak{m}},$$

where

- $I(\mathfrak{m})$  is the group generated by the fractional ideals of  $K$  which are coprime to  $\mathfrak{m}$ ; and
- $R_{\mathfrak{m}} = \langle \alpha \mathcal{O}_K : \alpha \equiv 1 \pmod{\mathfrak{m}}^* \rangle$  is the so-called ray modulo  $\mathfrak{m}$ , where  $\alpha \equiv 1 \pmod{\mathfrak{m}}^*$  means that both for  $\mathfrak{p} \mid \mathfrak{m}_0$  we have  $v_{\mathfrak{p}}(\alpha - 1) \geq v_{\mathfrak{p}}(\mathfrak{m}_0)$  and for  $\sigma \in \mathfrak{m}_\infty$  we have  $\sigma(\alpha) > 0$ .

**Example 10** (Ray class groups for  $\mathbb{Q}$ ). For  $K = \mathbb{Q}$  what do we get? Consider  $\mathfrak{m} = \langle m \rangle$ , then

$$\text{Cl}_{\mathfrak{m}} = (\mathbb{Z}/m\mathbb{Z})^\times / \langle \pm 1 \rangle.$$

If we add the infinite place and consider  $\mathfrak{m} = \langle m \rangle \cdot \infty$  then

$$\text{Cl}_{\mathfrak{m}} = \mathbb{Z}/m\mathbb{Z}^\times.$$

So we’ve already seen these!

Since the set of principal ideals coprime to  $\mathfrak{m}$ , call it  $P(\mathfrak{m})$ , lies between  $I(\mathfrak{m})$  and  $R_{\mathfrak{m}}$ , we have a map

$$\text{Cl}_{\mathfrak{m}} \rightarrow \text{Cl}_K.$$

In fact this map is surjective, and moreover we obtain a short exact sequence

$$1 \longrightarrow (\mathcal{O}_K/\mathfrak{m})^\times / \text{im}(\mathcal{O}_K^\times) \longrightarrow \text{Cl}_{\mathfrak{m}} \longrightarrow \text{Cl}_K \longrightarrow 0,$$

where  $(\mathcal{O}_K/\mathfrak{m}\mathcal{O}_K)^\times = (\mathcal{O}_K/\mathfrak{m}_0)^\times \times \prod_{\sigma \in \mathfrak{m}_\infty} \langle -1 \rangle$ .

Every  $\mathfrak{m}$  gives rise to an analogue of the cyclotomic fields, called the ray class field modulo  $\mathfrak{m}$ , which we denote by  $H_\mathfrak{m}$ .

**Example 11.** Consider the sets enumerated by  $n \in \mathbb{Z}_{>0}$

$$S_n := \{p : p = x^2 + ny^2\}.$$

Then we know

$$S_1 = \{p : p = x^2 + y^2\} = \{p \equiv 1 \pmod{4}\}$$

which has density  $1/2$ . Moreover similar results are easy enough for  $n = 2, 3, 4$ . This is seen by considering the factorisation of  $p$  in  $\mathbb{Z}[\sqrt{-n}]$ . However when we get to  $n = 5$  there is a problem: the class group of  $\mathbb{Z}[\sqrt{-5}]$  is  $\mathbb{Z}/2\mathbb{Z}$  (not trivial), so factoring the prime  $p$  as an ideal is no longer sufficient.

**Definition 12.** For  $\mathfrak{m} = 1$  the field  $H = H_\mathfrak{m}$  is called the Hilbert class field, and  $\text{Cl}_K = \text{Cl}_\mathfrak{m} \cong \text{Gal}(H/K)$ .

## LECTURE 2 (STEVENHAGEN)

Recall what we said yesterday: Class field theory is the direct generalisation of the Kronecker–Weber theorem, which gives us direct control on the abelian extensions of the rational numbers. More precisely,  $L/\mathbb{Q}$  is abelian if and only if  $L \subseteq \mathbb{Q}(\zeta_m)$  for some  $m \in \mathbb{Z}_{>0}$ . This actually gives you concrete control over the splitting behaviour of primes in this field since

$$\begin{aligned} \mathbb{Z}/m\mathbb{Z}^\times &\rightarrow \text{Gal}(L/\mathbb{Q}) \\ p \pmod{m} &\mapsto \text{Frob}_p \end{aligned}$$

for  $p \nmid m$ .

**Definition 13.** The smallest  $m$  such that  $L \subseteq \mathbb{Q}(\zeta_m)$  is called the conductor of  $L/\mathbb{Q}$  and will be written  $m_L$ .

*Remark 14.* Note that  $\mathbb{Q}(\zeta_m)$  needn't have conductor  $m$ :  $\mathbb{Q}(\zeta_{10})$  has conductor 5, for example.

This all generalises as follows.

**Theorem 15** (Class Field Theory).  *$K$  a number field then  $L/K$  is abelian if and only if  $L \subseteq K_\mathfrak{m}$  for some modulus  $\mathfrak{m}$  of  $K$  (where  $K_\mathfrak{m}$  is the ray class field modulo  $\mathfrak{m}$ ). We have a map*

$$\begin{aligned} \text{Cl}_\mathfrak{m} &\rightarrow \text{Gal}(L/K) \\ [\mathfrak{p}] &\mapsto \text{Frob}_\mathfrak{p} \end{aligned}$$

*which is an isomorphism if  $L = K_\mathfrak{m}$ .*

Let  $\mathfrak{m}$  be a modulus of  $K$  and note that  $\mathfrak{m} = \mathfrak{m}_0\mathfrak{m}_\infty = \prod_{\mathfrak{p} \leq \infty} \mathfrak{p}^{n(\mathfrak{p})}$  and satisfies

$$n(\mathfrak{p}) \begin{cases} = 0 & \text{almost everywhere;} \\ = 0 & \text{for complex places;} \\ \leq 1 & \text{for real places.} \end{cases}$$

By definition,  $\alpha \equiv 1 \pmod^* \mathfrak{m}$  if and only if  $v_\mathfrak{p}(\alpha - 1) \geq n(\mathfrak{p})$  and  $\sigma(\alpha) > 0$  for real places  $\sigma$  such that  $n(\sigma) = 1$ .

We have a sequence

$$\mathcal{O}_K^\times \longrightarrow \mathcal{O}_K/\mathfrak{m}^\times \longrightarrow \text{Cl}_\mathfrak{m} \longrightarrow \text{Cl}_K \longrightarrow 0.$$

**Definition 16.** For  $L/K$  abelian, the conductor is  $\mathfrak{m}_{L/K}$  which is the minimal modulus such that  $L \subseteq K_\mathfrak{m}$ .

Below are some properties of the conductor:

- $\mathfrak{p} \mid \mathfrak{m}_{L/K}$  if and only if  $\mathfrak{p}$  ramifies (by convention, a real embedding ramifies in  $L/K$  if its extension to  $L$  is complex).
- $\mathfrak{p}^2 \mid \mathfrak{m}_{L/K}$  if and only if  $\mathfrak{p}$  is wildly ramified (meaning the ramification index  $e_{L/K} \equiv 0 \pmod{p}$  for  $p$  the prime number below  $\mathfrak{p}$ ).

Recall the norm map  $N_{L/K} : L^\times \rightarrow K^\times$ , which can be extended to the ideals  $I_L \rightarrow I_K$  and maps  $\mathfrak{q} \mid \mathfrak{p}$  via  $\mathfrak{q} \mapsto N_{L/K}\mathfrak{q} = \mathfrak{p}^{f(\mathfrak{q}/\mathfrak{p})}$ . Using this we can define Artin's reciprocity law.

**Theorem 17** (Artin's reciprocity law). *The maps on Frobenii above induce an isomorphism*

$$\frac{I_K(\mathfrak{m})}{N_{L/K}I_L(\mathfrak{m}) \cdot R_\mathfrak{m}} \cong \text{Gal}(L/K).$$

**Maximal Abelian Extensions.** The maximal abelian extension of  $\mathbb{Q}$ , denoted  $\mathbb{Q}^{\text{ab}}$ , is, by the Kronecker–Weber theorem, equal to  $\cup_{n \geq 1} \mathbb{Q}(\zeta_n)$ . In fact

$$\text{Gal}(\mathbb{Q}^{\text{ab}}/\mathbb{Q}) \cong \widehat{\mathbb{Z}}^\times.$$

## 1. IDELES

Let  $K$  be a number field. Define the notation

**Notation 18.** For a prime ideal  $\mathfrak{p}$ , we let  $A_\mathfrak{p}$  be the integers in the completion  $K_\mathfrak{p}$  and  $U_\mathfrak{p}$  be the units of  $A_\mathfrak{p}$ . For  $n \geq 1$  we write  $U_\mathfrak{p}^{(n)} = 1 + \mathfrak{p}^n \subseteq U_\mathfrak{p} = U_\mathfrak{p}^{(0)}$ . We will write  $\pi_\mathfrak{p}$  for a uniformizer of  $A_\mathfrak{p}$ .

For an infinite place  $v$ , if  $v$  is complex then we define  $U_\mathfrak{p}^{(0)} = \mathbb{C}^\times$  and if it is real then  $U_\mathfrak{p}^{(0)} = \mathbb{R}^\times$  and  $U_{\mathfrak{p}(1)} = \mathbb{R}_{>0}$ .

**Definition 19.** The adèle ring is the restricted product

$$\mathbb{A}_K = \prod_{\mathfrak{p} \leq \infty}^{\prime} K_\mathfrak{p} = \{(x_\mathfrak{p})_\mathfrak{p} : x_\mathfrak{p} \in A_\mathfrak{p} \text{ for almost all } \mathfrak{p}\}.$$

The idèle group is the restricted product

$$\mathbb{A}_K^* = \prod_{\mathfrak{p} \leq \infty}^{\prime} K_\mathfrak{p}^* = \{(x_\mathfrak{p})_\mathfrak{p} : x_\mathfrak{p} \in U_\mathfrak{p} \text{ for almost all } \mathfrak{p}\}.$$

These groups come with natural product topologies.

**Definition 20.** For a finite abelian extension  $L/K$  the Artin map is defined by

$$\begin{aligned} \mathbb{A}_K^\times &\rightarrow \text{Gal}(L/K) \\ \pi_\mathfrak{p} &\mapsto \text{Frob}_\mathfrak{p} \end{aligned}$$

for  $\mathfrak{p} \nmid \mathfrak{m}_{L/K}$ , where  $\pi_\mathfrak{p}$  is identified with  $(1, \dots, 1, \pi_\mathfrak{p}, 1, \dots, 1)$ .

**Definition 21.** For a modulus  $\mathfrak{m} = \prod_{\mathfrak{p} \leq \infty} \mathfrak{p}^{n(\mathfrak{p})}$  we define the subgroup  $W_{\mathfrak{m}} \subset \mathbb{A}_K^\times$  by

$$W_{\mathfrak{m}} = \prod_{\mathfrak{p} \leq \infty} U_{\mathfrak{p}}^{(n(\mathfrak{p}))}$$

**Lemma 22.**  $H \subset \mathbb{A}_K^\times$  is an open subgroup if and only if  $H \supset W_{\mathfrak{m}}$  for some modulus  $\mathfrak{m}$ .

The key lemma is

**Lemma 23.** For every modulus  $\mathfrak{m}$ , there is an isomorphism

$$\begin{aligned} \mathbb{A}_K^\times / (K^* W_{\mathfrak{m}}) &\cong \text{Cl}_{\mathfrak{m}} \\ [\pi_{\mathfrak{p}}] &\mapsto [\mathfrak{p}], \end{aligned}$$

for  $\mathfrak{p} \nmid \mathfrak{m}$ .

*Proof.* Exercise. □

**Definition 24.** The idèle class group of  $K$  is  $\mathbb{A}_K^\times / K^\times$ .

Another way to phrase class field theory is the following.

**Theorem 25.**

$$\{K^{\text{ab}} \supset L \supset K\} \leftrightarrow \{\text{Open subgroups of } \mathbb{A}_K^\times / K^\times\}.$$

Moreover  $L$  corresponds to  $K^\times N_{L/K} \mathbb{A}_L^\times \pmod{K^\times}$ .

*Remark 26.* Note that  $\mathbb{A}_L = L \otimes \mathbb{A}_K$ , and so in particular there is a natural norm map  $N_{L/K} : \mathbb{A}_L \rightarrow \mathbb{A}_K$  which restricts on  $L^\times \subset \mathbb{A}_L$  to the usual norm map to  $K$ .

**Example 27.** Consider  $K = \mathbb{Q}$ . Then  $\mathbb{A}_{\mathbb{Q}}^\times = \prod_p' \mathbb{Q}_p^\times \times \mathbb{R}$ . In fact it is not hard to construct the isomorphism

$$\widehat{\mathbb{Z}}^\times \times \mathbb{R}_{>0} = \prod_p \mathbb{Z}_p^* \times \mathbb{R}_{>0} \cong \mathbb{A}_{\mathbb{Q}}^\times / \mathbb{Q}.$$

Precisely: let  $f : \mathbb{A}_{\mathbb{Q}}^\times \rightarrow \mathbb{Q}^\times$  be defined by  $f((x_v)_v) = \text{sgn}(x_\infty) \prod_p p^{v_p(x_p)}$ , and then define our map  $\mathbb{A}_{\mathbb{Q}}^\times \rightarrow \widehat{\mathbb{Z}} \times \mathbb{R}_{>0}$  to be

$$((x_p)_p, x_\infty) \mapsto \left( \frac{x_w}{f((x_v)_v)} \right)_w.$$

Note that the kernel has to be  $\mathbb{Q}$  by construction.

The discriminant of an abelian extension  $L/K$  can be written as

$$\Delta_{L/K} = \prod_{\chi \in \widehat{G}} \mathfrak{m}_\chi,$$

where for a character  $\chi \in \widehat{G}$   $\mathfrak{m}_\chi$  is the conductor of the subfield  $L^{\ker(\chi)} \subset L$ .

**Example 28.**  $\Delta_{\mathbb{Q}(\zeta_p)/\mathbb{Q}} = \pm p^{p-2}$

**Theorem 29** (Local-Global). *The diagram below commutes for every abelian extension  $L/K$ , every  $\mathfrak{p}$  of  $K$  and  $\mathfrak{q}$  of  $L$  such that  $\mathfrak{q} \mid \mathfrak{p}$ .*

$$\begin{array}{ccc} \mathbb{A}_K^\times / N_{L/K} \mathbb{A}_L^\times \cdot K^\times & \xrightarrow{\sim} & \text{Gal}(L/K) \\ \uparrow & & \uparrow \\ K_{\mathfrak{p}}^\times / N_{L/K} L_{\mathfrak{q}}^\times & \xrightarrow{\sim} & \text{Gal}(L_{\mathfrak{q}}/K_{\mathfrak{p}}). \end{array}$$

1.1. **Euler's Conjectures.** Below are questions and observations of Euler.

- (1) For  $p \equiv 1 \pmod{3}$ , is  $2 \in \mathbb{F}_p^{\times 3}$ ? This is equivalent to  $p = x^2 + 27y^2$  for  $x, y \in \mathbb{Z}$
- (2) For  $p \equiv 1 \pmod{4}$ , is  $2 \in \mathbb{F}_p^{\times 4}$ ? This is equivalent to  $p = x^2 + 64y^2$  for  $x, y \in \mathbb{Z}$ .

Using our modern class field theoretic knowledge, we can take the following perspective. 1 is determined by the splitting behaviour of  $p$  in  $x^3 - 2$ , and similarly 2 is determined by the splitting behaviour of  $p$  in  $x^4 - 2$ .

We leave this as an exercise in the interest of time.

### LECTURE 3 (SCHOOF): CLASS FIELD THEORY VIA GROUP COHOMOLOGY

This goes back to the Artin–Tate seminar in the 1950's, but you can find it in Cassels–Fröhlich, or in Serre's *Corps Locaux*. We will begin by talking about group cohomology.

#### GROUP COHOMOLOGY

Let  $G$  be a finite group and  $\mathbb{Z}[G]$  the group ring. We have the category of (left)  $\mathbb{Z}[G]$ -modules,  $\text{Gmod}$ , (sometimes we will just say  $G$ -modules), and a functor

$$\text{Gmod} \rightarrow \text{Ab}$$

given by  $M \mapsto M^G = \{m \in M : \sigma(m) = m \forall \sigma \in G\}$ . We have right derived functors of this

$$M \mapsto H^k(G, M),$$

where for  $k = 0$  note  $H^0(G, M) = M^G$ . We call these groups the cohomology groups. Moreover every short exact sequence in  $\text{Gmod}$

$$0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0,$$

gives a long exact sequence of cohomology groups.

**How are these constructed?** Take a free resolution of  $\mathbb{Z}$ , with trivial  $G$  action,

$$\cdots \rightarrow F_1 \rightarrow F_0 \rightarrow \mathbb{Z} \rightarrow 0.$$

Apply  $\text{Hom}_G(-, M)$  to this for  $M$  your  $G$ -module, and then take the cohomology of the complex

$$0 \longrightarrow \text{Hom}_G(F_0, M) \xrightarrow{\partial} \text{Hom}_G(F_1, M) \xrightarrow{\partial} \text{Hom}_G(F_2, M) \xrightarrow{\partial} \text{Hom}_G \cdots,$$

meaning that you take the group  $\ker(\partial)/\text{im}(\partial)$  in  $\text{Hom}_G(F_k, M)$  and call it  $H^k(G, M)$ .

This is nice, and doesn't depend on the choice of complex. Generally we prefer to take the standard complex, which is given as follows.

$$F_i = \mathbb{Z}[G^{i+1}]$$

with the maps

$$\partial : F_n \rightarrow F_{n-1}$$

given by  $(g_1, \dots, g_{n+1}) \mapsto \sum_{i=1}^{n+1} (-1)^i (g_1, \dots, \widehat{g_i}, \dots, g_{n+1})$ , where the hat means that we exclude this term. Some example computations with this are as follows.

**Example 30.**

$$\begin{aligned} H^0(G, M) &= M^G \\ H^1(G, M) &= \frac{\{f : G \rightarrow M : f(\sigma\tau) = \sigma(f(\tau)) + f(\sigma)\}}{\{\sigma \mapsto \sigma(m) - m : m \in M\}} \end{aligned}$$

An explicit one:

$$H^1(G, \mathbb{Z}) = \text{Hom}(G, \mathbb{Z}) = 0.$$

Another:

$$H^1(G, \mathbb{Q}/\mathbb{Z}) = \text{Hom}(G, \mathbb{Q}/\mathbb{Z}) \cong G_{\text{ab}}^{\text{dual}}$$

A useful result about these groups is the following.

**Theorem 31** (Hilbert 90). *Let  $L/K$  be a finite Galois extension with Galois group  $G$ . Then*

$$H^1(G, L^\times) = 0.$$

*Proof.* For a 1-cocycle  $f$ , note that by the linear independence of automorphisms of fields, the sum  $\sum_{\sigma \in G} f(\sigma)\sigma \neq 0$  is a nonzero map  $L^\times \rightarrow L^\times$ . Take  $\alpha \in L^\times$  with nonzero image and define

$$\beta := \sum_{\sigma \in G} f(\sigma)\sigma(\alpha) \neq 0.$$

Then for  $\tau \in G$  note that

$$\tau(\beta) = \prod_{\sigma \in G} \tau(f(\sigma))\tau\sigma(\alpha) = \frac{1}{f(\tau)} \prod_{\sigma \in G} f(\tau\sigma)\tau\sigma(\alpha) = \frac{1}{f(\tau)}\beta.$$

In particular,  $f$  is the coboundary  $\tau \mapsto \beta/\tau(\beta)$ . □

**Induced Modules.** It is quite easy to show that if  $M$  is a free  $\mathbb{Z}[G]$ -module, then for all  $q \geq 1$

$$H^q(G, M) = 0.$$

Moreover, there is the notion of an induced  $G$ -module:

$$M = \mathbb{Z}[G] \otimes X$$

where  $X$  is any abelian group. This module also satisfies, for all  $q \geq 1$ ,

$$H^q(G, M) = 0.$$

Note that these are enough to conclude that if  $L/K$  is finite Galois with Galois group  $G$  then for all  $q \geq 1$

$$H^q(G, L) = 0,$$

since  $L \cong K[G] = K \otimes \mathbb{Z}[G]$ .

**Tate Cohomology.** These groups are  $\hat{H}^k(G, M)$  for  $k \in \mathbb{Z}$ , where for  $k > 0$  we define  $\hat{H}^k(G, M) := H^k(G, M)$ . For nonpositive  $k$  we need to do some defining. We do this with a complete resolution.

$$\begin{array}{ccccccc}
 \dots & \longrightarrow & \mathbb{Z}[G^2] & \longrightarrow & \mathbb{Z}[G] & \xrightarrow{N_G = \sum_{\sigma \in G} \sigma} & \mathbb{Z}[G] \longrightarrow \mathbb{Z}[G^2] \longrightarrow \dots \\
 & & & & \searrow \sigma \mapsto 1 & & \nearrow \\
 & & & & \mathbb{Z} & & \\
 & & \nearrow & & & & \searrow \\
 0 & & & & & & 0
 \end{array}$$

As before, apply  $\text{Hom}_G(-, M)$  and take the cohomology of the complex on the top line. As some special computational cases we have

$$\hat{H}^k(G, M) = \begin{cases} H^k(G, M) & \text{if } k \geq 1 \\ M^G / N_G(M) & \text{if } k = 0 \\ \ker(N_G) / \{(\sigma - 1)m : m \in M, \sigma \in G\} & \text{if } k = -1 \\ H_{-k-1}(G, M) & \text{if } k \leq -2 \end{cases}$$

where the final groups for the negative case are homology groups, obtained by a similar construction to cohomology but using the covariants functor.

**Example 32** (Trivial Module).

$$\begin{aligned}
 H^1(G, \mathbb{Z}) &= 0 \\
 \hat{H}^0(G, \mathbb{Z}) &= \mathbb{Z} / \#G\mathbb{Z} \\
 \hat{H}^{-1}(G, \mathbb{Z}) &= 0 \\
 \hat{H}^{-2}(G, \mathbb{Z}) &= \hat{H}^{-1}(G, I) \cong I / I^2 \cong G_{\text{ab}}
 \end{aligned}$$

where  $I := \langle \sigma - 1 : \sigma \in G \rangle \subseteq \mathbb{Z}[G]$  is the augmentation ideal. The final isomorphism is given in reverse by  $\sigma \mapsto (\sigma - 1)$

#### LOCAL CLASS FIELD THEORY

Let  $L/K$  be a finite Galois extension of local fields with  $G = \text{Gal}(L/K)$ , and write  $n = \#G$ . There are canonical isomorphisms for all  $q \in \mathbb{Z}$ :

$$\hat{H}^q(G, \mathbb{Z}) \xrightarrow{\sim} \hat{H}^{q+2}(G, L^\times)$$

As examples note that for  $q = -1$  we get  $0 = 0$  and for  $q = 0$  we obtain  $\mathbb{Z}/n\mathbb{Z} = H^2(G, L^\times)$ . For  $q = -2$  we obtain

$$G_{\text{ab}} \cong K^\times / N_{L/K} L^\times$$

which we refer to as the reciprocity isomorphism.

**The Isomorphism.** How is this isomorphism defined?

**Definition 33.** We have pairings for  $M, N \in \text{Gmod}$

$$\hat{H}^p(G, M) \otimes \hat{H}^q(G, N) \rightarrow \hat{H}^{p+q}(G, M \otimes N)$$

referred to as the cup products.

Then the isomorphisms above are given by the cup product

$$\hat{H}^q(G, \mathbb{Z}) \otimes \hat{H}^2(G, L^\times) \rightarrow \hat{H}^{q+2}(G, L^\times)$$

where we cup with the element  $1 \in \mathbb{Z}/n\mathbb{Z} \cong H^2(G, L^\times)$  where the isomorphism is the precise one above.

### GLOBAL CLASS FIELD THEORY

If  $L/K$  is a finite Galois extension of number fields, and  $G = \text{Gal}(L/K)$  and  $n = \#G$  as before, then this works out similarly but now with the Idèle class group.

$$\hat{H}^q(G, \mathbb{Z}) \xrightarrow{\sim} \hat{H}^{q+2}(G, \mathbb{A}_L^\times / L^\times) .$$

For  $q = -1$  we again get  $0 = 0$ , because  $H^1(G, \mathbb{A}_L^\times / L^\times) = 0$ .

### Dimension Shifting.

**Proposition 34** (Dimension Shifting). *For every  $M \in \text{Gmod}$ , there exists a module  $J$  with trivial cohomology and  $M \subseteq J$ , and similarly there is a  $J'$  with trivial cohomology and a surjection  $M \rightarrow J'$ .*

*Proof.* Set

$$\begin{aligned} J' &= M \otimes \mathbb{Z}[G] \rightarrow M \\ m \otimes \sigma &\mapsto \sigma(m) \\ M &\rightarrow J = \text{Hom}(\mathbb{Z}[G], M) \\ m &\mapsto (\sigma \mapsto \sigma^{-1}(m)) \end{aligned}$$

Note that these are cohomologically trivial because they are induced. □

This allows us to take short exact sequences

$$0 \longrightarrow \ker \longrightarrow J' \longrightarrow M \longrightarrow 0,$$

and

$$0 \longrightarrow M \longrightarrow J \longrightarrow \text{coker} \longrightarrow 0,$$

and compute cohomology. Since the middle terms are cohomologically trivial we get isomorphisms

$$\begin{aligned} \hat{H}^q(G, M) &\cong \hat{H}^{q+1}(G, \ker), \\ \hat{H}^q(G, M) &\cong \hat{H}^{q-1}(G, \text{coker}). \end{aligned}$$

and equate cohomology of  $M$  with that which is one degree lower (resp. higher) of the cokernel (resp. kernel). This is why we call it ‘dimension shifting’: we can increase or decrease the cohomological degree somewhat freely by switching the module. An example application is the following corollary.

**Corollary 35.** *For all  $q \in \mathbb{Z}$ , and all  $M \in \text{Gmod}$ , the group  $\hat{H}^q(G, M)$  is  $\#G$ -torsion.*

*Proof.* By dimension shifting (Proposition 34) it is sufficient to prove this for  $q = 0$ , and in this case

$$\widehat{H}^q(G, M) = M^G / N_G(M).$$

For  $m \in M^G$  note that  $\#G \cdot m = N_G(m)$ , showing the result.  $\square$

**Class Field Theory.** Ok, returning to Class Field Theory. We have an exact grid

$$\begin{array}{ccccccc}
 & & 0 & & 0 & & 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 0 & \longrightarrow & \mathcal{O}_L^\times & \longrightarrow & L^\times & \longrightarrow & \mathrm{PId}_L \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 0 & \longrightarrow & U_L & \longrightarrow & \mathbb{A}_L^\times & \longrightarrow & I_L \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 0 & \longrightarrow & Q_L & \longrightarrow & \mathbb{A}_L^\times / L^\times & \longrightarrow & \mathrm{Cl}_L \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 & & 0 & & 0 & & 0
 \end{array}$$

where

$$\begin{aligned}
 \mathbb{A}_L^\times &\rightarrow I_L \\
 (x_{\mathfrak{p}}) &\mapsto \prod_{\mathfrak{p}} \mathfrak{p}^{v_{\mathfrak{p}}(x_{\mathfrak{p}})} \\
 U_L &:= \{(x_{\mathfrak{p}})_{\mathfrak{p}} \in \mathbb{A}_L^\times : v_{\mathfrak{p}}(x_{\mathfrak{p}}) = 0 \ \forall \mathfrak{p}\}.
 \end{aligned}$$

People usually do class field theory by going from the top left to bottom right via the L-shape in the top right of this diagram. In fact it is much easier to to the bottom left!

$$0 \longrightarrow \mathcal{O}_L^\times \longrightarrow U_L \longrightarrow \mathbb{A}_L^\times / L^\times \longrightarrow \mathrm{Cl}_L \longrightarrow 0 .$$

Global class field theory is obtained by studying the cohomology of the idèle class group  $\mathbb{A}_L^\times / L^\times$ . It is in some sense proved using local class field theory. Where does this come in? Note that the  $U_L$  term satisfies  $U_L = \prod_{\mathfrak{p}} \mathcal{O}_{\mathfrak{p}}^\times$  and there is the sequence

$$0 \rightarrow \mathcal{O}_{\mathfrak{p}}^\times \rightarrow K_{\mathfrak{p}}^\times \rightarrow \mathbb{Z} \rightarrow 0$$

which relates

$$\widehat{H}^q(G, U_L) = \prod_{\mathfrak{p}} \widehat{H}^q(G_{\mathfrak{p}}, \mathcal{O}_{\mathfrak{p}}^\times)$$

to  $\widehat{H}^q(G, K_{\mathfrak{p}}^\times)$ , which is the main object of study in local class field theory.

#### LECTURE 4 (STEVENHAGEN)

Let  $K$  be a number field, and  $L/K$  a finite Galois extension. Recall that we have seen Artin's reciprocity law.

**Theorem 36** (Artin Reciprocity). *If  $\mathfrak{m} = \mathfrak{m}_{L/K}$  is the conductor, then there is a unique continuous surjection*

$$\begin{array}{ccccc} K_{\mathfrak{p}} & \longrightarrow & \mathbb{A}_K^{\times}/K^{\times} & \longrightarrow & \text{Gal}(L/K) \\ & & \downarrow & & \uparrow \\ & & \mathbb{A}_K^{\times}/K^{\times}W_{\mathfrak{m}} & \xrightarrow{\sim} & \text{Cl}_{\mathfrak{m}} \end{array}$$

where the top row composes to send, for  $\mathfrak{p}$  an unramified prime,

$$\pi_{\mathfrak{p}} \mapsto \text{Frob}_{\mathfrak{p}}.$$

This is the only theorem you need to remember for Global Class Field Theory. In fact this induces

$$\begin{array}{ccc} \mathbb{A}_K^{\times}/K^{\times}N_{L/K}\mathbb{A}_L^{\times} & \xrightarrow{\sim} & \text{Gal}(L/K) \\ \uparrow & & \uparrow \\ K_{\mathfrak{p}}^{\times}/N_{L_{\mathfrak{q}}/K_{\mathfrak{p}}}L_{\mathfrak{q}}^{\times} & \xrightarrow{\sim} & G_{\mathfrak{p}} \end{array}$$

where the vertical arrows are injections.

*Exercise 37.* Show that

- $\mathfrak{p}$  unramified means that  $N(U_{\mathfrak{q}}) = U_{\mathfrak{p}} = U_{\mathfrak{p}}^{(0)}$ ;
- $\mathfrak{p}$  tamely ramified means that  $N(U_{\mathfrak{q}}) \supset 1 + \mathfrak{p} = U_{\mathfrak{p}}^{(1)}$

**Question 38.** *Why is this called reciprocity?*

Let us make an extended example. Consider the legendre symbol for  $a \in \mathbb{Z}$ ,  $p \nmid 2a$  a prime then

$$\left(\frac{a}{p}\right) = \begin{cases} 1 & \text{if } a \in \mathbb{F}_p^{\times 2} \\ -1 & \text{if } a \notin \mathbb{F}_p^{\times 2} \end{cases}$$

Note that this precisely determines the splitting behaviour of  $p$  in  $\mathbb{Q}(\sqrt{a})$ .

**Theorem 39** (Euler).

$$\left(\frac{a}{p}\right) \equiv a^{\frac{p-1}{2}} \pmod{p}$$

**Definition 40.**

$$\left(\frac{a}{p}\right) = \frac{\text{Frob}_p(\sqrt{a})}{\sqrt{a}}$$

In fact the conductor of  $\mathbb{Q}(\sqrt{a})/\mathbb{Q}$  is exactly the discriminant.

**Conjecture 41** (Euler (experimentally)).  $\left(\frac{a}{p}\right)$  only depends on  $p \in \mathbb{Z}/4a\mathbb{Z}^{\times}$ . Moreover, if  $a > 0$  then the same is true but we only need to look in  $(\mathbb{Z}/4a\mathbb{Z}^{\times})/\{\pm 1\}$ .

This is proved in Gauss' quadratic reciprocity law.

**Theorem 42** (Gauss' Quadratic Reciprocity Law). *if  $p \neq q$  are odd primes then*

$$\left(\frac{p}{q}\right)\left(\frac{q}{p}\right) = (-1)^{\frac{(p-1)(q-1)}{2}}.$$

Note that if  $p$  is odd and  $p^* = \pm p$  is the choice for which  $p \equiv 1 \pmod{4}$ , then we have a diagram of the form

$$\begin{array}{c} \mathbb{Q}(\zeta_p) \\ | \\ \mathbb{Q}(\sqrt{p^*}) \\ | \\ \mathbb{Q} \end{array}$$

in which the splitting behaviour of  $q$  determines  $(-1)^{(q-1)/2} \left(\frac{p}{q}\right)$ . If one of our primes is 2 then the associated diagram of fields is a little more complicated:

$$\begin{array}{ccccc} & & \mathbb{Q}(\zeta_8) & & \\ & \swarrow & | & \searrow & \\ \mathbb{Q}(\sqrt{-1}) & & \mathbb{Q}(\sqrt{-2}) & & \mathbb{Q}(\sqrt{2}) \\ & \searrow & | & \swarrow & \\ & & \mathbb{Q} & & \end{array}$$

*Proof of Quadratic Reciprocity.* If  $p \not\equiv q \pmod{4}$  then  $p + q = 4a > 0$ . Then

$$\left(\frac{p}{q}\right) = \left(\frac{p+q}{q}\right) = \left(\frac{4a}{q}\right) = \left(\frac{a}{q}\right) = \left(\frac{a}{p}\right) = \left(\frac{q}{p}\right).$$

Else if they are the same then do the same but with  $p - q$ . □

**Question 43.** *How do we create some kind of higher reciprocity?*

Maybe you want to define cubic reciprocity, so you take a prime  $p \equiv 1 \pmod{3}$  and define  $\left(\frac{2}{p}\right)_3$  to be 1 if 2 is a cube mod  $p$ . Then this is 1 if and only if  $p = x^2 + 27y^2$ .

Maybe since we're looking at cube roots, we should look at a field (instead of  $\mathbb{Q}$ ) which has third roots of unity, i.e.  $K = \mathbb{Q}(\zeta_3)$ . Then if  $\mathfrak{p} \nmid 3$  we must have  $3 \mid \#k_{\mathfrak{p}}$ , and we can define a legendre-type symbol as above and show

$$\langle \zeta_3 \rangle \ni \left(\frac{\alpha}{\mathfrak{p}}\right)_3 \equiv \alpha^{(N(\mathfrak{p})-1)/3}.$$

This is equivalent to the following.

**Definition 44.** define

$$\left(\frac{\alpha}{\mathfrak{p}}\right)_3 = \frac{\text{Frob}_{\mathfrak{p}}(\sqrt[3]{\alpha})}{\sqrt[3]{\alpha}},$$

where the Frobenius is in the extension  $K(\sqrt[3]{\alpha})/K$ .

Note that again this is determined by splitting behaviour of  $\mathfrak{p}$ .

**Kummer Theory.** Let  $F$  be a field such that  $\zeta_n \in F^\times$ . Then there is a bijection between

$$\{E/F : \text{finite Galois with } n\text{Gal}(E/F) = 0\}$$

and

$$\{F^{\times n} \subseteq W \subseteq F^\times\}.$$

This is given by  $W \mapsto F(\sqrt[n]{W})$ , and  $E \mapsto E^{\times n} \cap F^\times$ . Note we have a pairing

$$\text{Gal}(E/F) \times W/F^{\times n} \rightarrow \langle \zeta_n \rangle$$

given by  $(\sigma, w) \mapsto \sigma(\sqrt[n]{W})/\sqrt[n]{W}$ . Using class field theory to identify  $\text{Gal}(E/F)$  with  $F^\times/N_{E/F}E^\times$  we obtain a pairing induced by

$$F^\times/F^{\times n} \times F^\times/F^{\times n} \rightarrow \langle \zeta_n \rangle$$

$$(\alpha, \beta) \mapsto \frac{\sigma_\alpha(\sqrt[n]{\beta})}{\sqrt[n]{\beta}} =: (\alpha, \beta)_{F,n}.$$

We call this the norm residue symbol. Below are some properties of this.

- $(\alpha, \beta)_{F,n} = 1$  if and only if  $a \in N(F(\sqrt[n]{\beta})^\times)$ .
- $(-\beta, \beta)_{F,n} = 1 = (1 - \beta, \beta)_{F,n}$ .
- $(\alpha, \beta)_{F,n} = 1$  if  $\alpha, \beta, n \in U_F$ .
- $(\alpha, \beta)_{F,n} = (\beta, \alpha)_{F,n}^{-1}$ . This follows from the second property. A proof:

$$1 = (\alpha\beta, -\alpha\beta)_{F,n} = (\alpha, -\alpha)_{F,n} (\alpha, \beta)_{F,n} (\beta, \alpha)_{F,n} (\beta, -\beta)_{F,n} = (\alpha, \beta)_{F,n} (\beta, \alpha)_{F,n}$$

**Return to CFT.** Assume that  $\zeta_n \in K^\times$ .

**Definition 45.** Let  $S = \{\mathfrak{p} : \mathfrak{p} \mid n\infty\}$ , and for  $\alpha \in K^\times$  let  $S(\alpha) = S \cup \{\mathfrak{p} : v_{\mathfrak{p}}(\alpha) \neq 0\}$ . Define the  $n$ th power residue symbol for  $\mathfrak{p} \in S(\alpha)$  by

$$\left(\frac{\alpha}{\mathfrak{p}}\right)_n = \frac{\text{Frob}_{\mathfrak{p}}(\sqrt[n]{\alpha})}{\sqrt[n]{\alpha}} \in \langle \zeta_n \rangle,$$

where Frobenius is in  $K(\sqrt[n]{\alpha})/K$  which is unramified for  $\mathfrak{p} \in S(\alpha)$  and abelian of exponent  $n$ .

*Remark 46.* Note that this symbol only depends on  $[\mathfrak{p}] \in \text{Cl}_{K,\mathfrak{p}}$  where we take  $\mathfrak{m} \mid n^* \{\mathfrak{p} : v_{\mathfrak{p}}(\alpha) \neq 0 \pmod n\}$ .

We can then define a more general symbol multiplicatively.

**Definition 47.** We define the ‘ $n$ -power Jacobi symbol’ to be

$$\left(\frac{\alpha}{\beta}\right)_n = \prod_{\mathfrak{p} \notin S(\alpha)} \left(\frac{\alpha}{\mathfrak{p}}\right)_n^{v_{\mathfrak{p}}(\beta)}.$$

**Theorem 48** (Power Reciprocity Law).

$$\left(\frac{\alpha}{\beta}\right)_n \left(\frac{\beta}{\alpha}\right)_n^{-1} = \prod_{\mathfrak{p} \in S(\alpha) \cap S(\beta)} (\alpha, \beta)_{n,\mathfrak{p}},$$

where  $(\alpha, \beta)_{n,\mathfrak{p}}$  is the  $n$  norm residue symbol above for  $K_{\mathfrak{p}}$ .

**Example 49.** If  $K = \mathbb{Q}$ ,  $n = 2$ ,  $a, b$  both odd, then

$$\left(\frac{a}{b}\right)_2 \left(\frac{b}{a}\right)_2 = (a, b)_2 (a, b)_\infty.$$

For the pairing at 2 note that  $a, b \in \mathbb{Z}_2^\times$  by assumption, and  $\mathbb{Z}_2^\times/\mathbb{Z}_2^\times \cong \mathbb{Z}/8\mathbb{Z}^\times$ . Since this is generated by  $-1, 5$  we can compute to obtain that the symbol is given by

$$\begin{array}{c|cc} & -1 & 5 \\ \hline -1 & -1 & 1 \\ 5 & 1 & 1 \end{array}$$

For the infinite pairing we have  $\mathbb{R}^\times/\mathbb{R}^{\times 2} = \langle -1 \rangle$  and so the pairing is nontrivial if and only if both  $a, b < 0$ .

*Exercise 50.*  $n = 3$ ,  $K = \mathbb{Q}(\zeta_3) \supset \mathcal{O}_K = \mathbb{Z}[\zeta_3]$ ,  $\mathcal{O}_K^\times = \langle -\zeta_3 \rangle$ . This has class number 1, let  $\pi \in \mathcal{O}_K$  be a prime element with  $\pi \equiv 1 \pmod{3} = (1 - \zeta_3)^2$  then show that

$$\left( \frac{\pi_1}{\pi_2} \right)_3 = \left( \frac{\pi_2}{\pi_1} \right)_3.$$

Once you've done this, look at  $n = 4$ .

Quadratic reciprocity became trivial if you assumed class field theory, in fact the same is true for all of these reciprocity laws.

**Theorem 51** (Product Formula). *For  $\alpha, \beta \in K^\times \ni \zeta_n$ , then*

$$\prod_{\mathfrak{p} \leq \infty} (\alpha, \beta)_{n, \mathfrak{p}} = 1$$

How does this compare to Artin reciprocity?

*Proof.*

$$\begin{array}{ccc} \prod'_{\mathfrak{p} \leq \infty} K_{\mathfrak{p}}^\times & \longrightarrow & \oplus_{\mathfrak{p}} \text{Gal}(K_{\mathfrak{p}}(\sqrt[n]{\beta})/K) \\ \downarrow & & \downarrow (\sigma_{\mathfrak{p}}) \mapsto \prod_{\mathfrak{p}} \sigma_{\mathfrak{p}} \\ \mathbb{A}_K^\times / K^\times & \longrightarrow & \text{Gal}(K(\sqrt[n]{\beta})/K). \end{array}$$

Note that  $\alpha \in K$ , considered in the top left, gets mapped to the left hand side of the product formula if we go via the top right, and to 1 trivially if we go via the bottom left.  $\square$
